## 1 Array copy performance

I ran this test on my Late-2012 Mac Mini with a quad-core,  $2.3\,\mathrm{GHz}$  Intel Core i7-3615QM processor. This processor has  $64\,\mathrm{kB}$  L1 cache per core,  $256\,\mathrm{kB}$  L2 cache per core, and  $6\,\mathrm{MB}$  L3 cache which is shared between the cores. The computer has  $16\,\mathrm{GB}$  of RAM installed. The operating system is Mac OS X El Capitan (10.11.2).

All codes were compiled using the default Apple-provided Clang version 7.0.2 with optimization level -O2.

The results for this section are shown in Table 1. Note that I was unable to run the test for an array size of  $5\,000\,000$  since OS X sets a hard limit of  $65\,532\,\mathrm{kB}$  on the stack size which cannot be bypassed with ulimit -s.

The time results are plotted in Fig. 1, and the data rates are plotted in Fig. 2.

N	Time for Loop (s)	Rate (MB/s)
250	$4.76 \times 10^{-8}$	$8.40 \times 10^{4}$
1000	$1.80 \times 10^{-7}$	$8.89 \times 10^4$
5000	$1.85 \times 10^{-6}$	$4.33 \times 10^4$
10000	$3.63 \times 10^{-6}$	$4.41 \times 10^{4}$
50000	$2.28 \times 10^{-5}$	$3.51 \times 10^{4}$
100000	$4.52 \times 10^{-5}$	$3.54 \times 10^{4}$
500000	$3.68 \times 10^{-4}$	$2.17 \times 10^{4}$
1000000	$8.78 \times 10^{-4}$	$1.82 \times 10^{4}$
5000000	(Failed)	(Failed)

Table 1: Results from Part 1

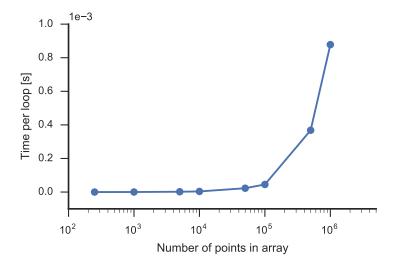

Figure 1: Time per loop for Part 1.

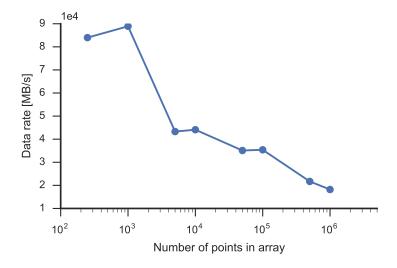

Figure 2: Data rate for Part 1.

Function	Best rate [GB/s]	Avg time [ms]	Min time [ms]	Max time [ms]
Copy	16.5	3.14	2.89	4.12
$\mathbf{Scale}$	12.3	4.25	3.92	5.28
$\mathbf{Add}$	12.7	5.99	5.67	6.41
Triad	12.7	6.09	5.66	6.62

Table 2: STREAM results

## 2 STREAM benchmark

I ran the C version of the STREAM benchmark on the same system as above, compiled as above with clang -02. The array size was set to 3000000, which produced an array size of 22.9 MiB. This is more than 4 times the size of the 6 MB L3 cache on this system.

The results of the benchmark are shown in Table 2.

## 3 Sparse matrix-vector multiply performance estimate

Based on the analysis in Lecture 4, the processor needs to load approximately 1 double and 1 integer for each floating point operation (assuming a single operation for multiply-add). This amounts to  $12\,\mathrm{B/FLOP}$ .

The STREAM results show that the processor can move about  $16.5\,\mathrm{GB/s}$  to or from memory. If the clock frequency is  $2.3\,\mathrm{GHz}$ , then this is  $7.2\,\mathrm{B/cycle}$ . Assuming the processor can perform  $1\,\mathrm{FLOP/cycle}$ , this means that it can move  $7.2\,\mathrm{B/FLOP}$ .

Thus, the expected performance is  $(7.2\,\mathrm{B/FLOP})/(12\,\mathrm{B/FLOP}) = 60\,\%$  of the peak performance. This equals  $0.6 \times 2.3\,\mathrm{GFLOPS} = 1.38\,\mathrm{GFLOPS}$ .
